Place and Pay for a Coffee Order

Lab 1 Use-Case Flow | Assumed scenario: campus self-service coffee kiosk

Primary actor	Customer
Supporting actors	Payment Gateway; Barista / Order Fulfillment
Precondition and success result	The kiosk is online and the selected items are available. On success, payment is approved, one preparation ticket is queued, and an order number is shown.

Main Success Scenario

1. The customer starts a new order; the system displays the drink menu and available sizes.
2. The customer selects a coffee type, a size, and any optional milk or syrup customizations.
3. The system checks availability, calculates the price, and displays the itemized order summary.
4. The customer reviews the summary and confirms the order.
5. The system sends the payment amount to the Payment Gateway.
6. The Payment Gateway approves payment and returns an authorization result.
7. The system records the paid order and queues exactly one preparation ticket for the Barista.
8. The system displays the order number and receipt to the customer; the use case ends successfully.

Alternate Flows

A1 - Item unavailable (at step 3). The system identifies the unavailable item and offers a replacement or removal. The customer updates the order and returns to step 3, or cancels; cancellation clears the order and no payment is requested.

A2 - Payment declined (at step 6). The system reports the decline and invites one retry with another payment method. If the retry is approved, continue at step 7. If it is declined again, the system cancels the order, clears the cart, and queues no preparation ticket.

End condition: either one paid order is queued and confirmed, or the order is cancelled without a preparation ticket.
